The Problem of Antimicrobial Resistance in the Food Chain

Recommendations
Based on the current safefood report the following recommendations were offered in support of the surveillance infrastructure and research requirements:

Surveillance:
- Intensify AMR surveillance in the animal population, across the food chain, and in the human population
- Integrate the all-island AMR Monitoring Programme (including prescribing, dispensing and consumption patterns in human and animal populations)
- Promote the prudent use of antimicrobial agents in animal and human medicine
- Establish a forum on AMR and food safety, including all stakeholders to insure delivery of the surveillance strategy

Research:
- Improve our understanding of the impacts of AMR on current and alternative food processing technologies
- Food attribution studies should be undertaken to determine the fraction of food animal-associated AMR infections on the island of Ireland and to assist with the identification and prioritisation of hazards posed

Background and terms of reference of the report

Background:
There is already considerable activity and information on antimicrobial resistance (AMR) at the beginning and end of the human food chain i.e. veterinary and clinical. However, the primary focus of this report is on food and food processing technology with particular impact on the consumer-health aspects. This theme is appropriate to the remit of safefood. This area is under explored, although there is some current scientific literature on the relationship between AMR, modern food production and consumer/food interaction. This review will inform and underpin any action to be undertaken by safefood on AMR and food safety.

Terms of reference of the report:
- The prevalence of AMR bacteria (pathogens and commensals) in the food chain
- The impact of food processing stresses on the survival and evolution of AMR bacteria within food and the transfer of AMR among bacteria within the food matrix
- The impact of currently used antimicrobials including disinfectants, sanitizers, surfactants and related decontamination treatments
- The human health impact of antimicrobial use in food animals

Background

Antimicrobial resistance (AMR) associated with the food chain is currently a subject of major interest to many food chain stakeholders. In response to the need of a better understanding of this area and to raise awareness of the issue, its primary focus is on the food chain when it impacts consumer health. This review will inform and underpin any future action to be taken in response to this issue.

What is antimicrobial resistance?

Antibiotics are important drugs used in the treatment of bacterial infections in both humans and animals. Emerging antibiotic resistance among certain bacteria is now frequently observed, thereby posing a serious threat to public health. Once these micro-organisms become resistant to one or more antibiotics, they do not respond to therapy. Some bacteria are naturally resistant, whilst others become resistant following selection after prolonged antibiotic use. Residues of resistant bacteria may develop in the gastrointestinal (GI) tracts of food-producing animals following mis-use of these important drugs. Furthermore, humans may also be exposed through direct contact with animals and humans that may be colonised/infected with AMR bacteria. A lesser recognised route however, is through the food chain, which may contain AMR bacteria derived from food-producing animals or from cross-contamination during food processing.

In this report, emphasis has been placed primarily on those bacteria of animal origin that infect humans via the food chain. Specifically this report reviews the scientific data available in relation to the food chain, particularly those that impact human health. The report summarises information on other AMR bacteria such as methicillin-resistant Staphylococcus aureus, Clostridium difficile and Enterococcus faecalis (VTEC), Cryptobacteriaceae spp., all of which are important zoonotic bacteria. The report considers how AMR bacteria may be dispersed via food and water, or from the spraying of food processing environments where they may be colonised/infected with AMR bacteria and enter the food chain. As AMR bacteria become resistant, following the stress imposed through antibiotic selection, they may evolve and undergo genetic changes which make these organisms more difficult to eliminate. This may in turn increase the likelihood of transmission through the food chain.

Some bacteria are naturally resistant, whilst others become resistant following selection after prolonged antibiotic use. Residues of resistant bacteria may develop in the gastrointestinal (GI) tracts of food-producing animals following mis-use of these valuable therapeutic drugs. These resistant bacteria can be transferred from food-producing animals such as cattle, pigs and poultry, and the environment to humans, via the food chain.

Emerging AMR: the potential exposure routes

1. Food-producing animals & the environment

AMR arises following the mis-use of antibiotics. Humans are exposed to acquire AMR bacteria through selective pressure associated with prolonged use of these important drugs. Furthermore, humans may also be exposed through direct contact with animals and humans that may be colonised/infected with AMR bacteria. A lesser recognised route however, is the food chain which may contain AMR bacteria derived from food-producing animals or from cross-contamination during food processing.

In the environment, AMR bacteria can enter the food chain through the contamination of ground and surface water, or from the spraying of food crops with contaminated water containing AMR bacteria derived from human and animal waste. Where these crops are not processed further after harvest, this food source may pose an increased risk to public health.

2. Food processing technologies

Food processing technologies are designed to reduce the risk of transmission of hazards including bacteria through the food chain. As bacteria become resistant, following the stress imposed through antibiotic selection, they may evolve and undergo genetic changes which make these organisms more difficult to eliminate. This may in turn increase the likelihood of transmission through the food chain.

3. Use of sanitizing agents & biocides in food processing environments

Sanitizers are used in the food industry to eliminate contaminating bacteria that may occur in food preparation surfaces or equipment in direct contact with food. Although sanitizers, biocides and antibiotics kill bacteria, there is increasing concern that resistance to these cleaning agents may directly or indirectly be linked to AMR. Concerns have been expressed in regard to the application of sanitizers and biocides in food processing and in domestic food preparation environments where they may promote the development and dissemination of AMR via the human food chain. Currently there is a need to develop a better understanding of this relationship.

Executive Summary

Antimicrobial resistance (AMR) associated with the food chain is currently a subject of major interest to many food chain stakeholders. In response to the need for a better understanding of this area and to raise awareness of the issue, its primary focus is on the food chain when it impacts consumer health. This review will inform and underpin any future action to be taken to address this issue.

Human health impact

There is a range of human health consequences from AMR including prolonged illnesses and even death. Individuals with impaired immunity are at greater risk.

Strategies to reduce the emergence of AMR bacteria

On the island of Ireland there are two AMR strategies currently active, the Strategy for the control of Antimicrobial Resistance in the Republic of Ireland (SARI) and the Antimicrobial Resistance Action Plan (AMRAP) in Northern Ireland. Both strategies have recommended the development of guidance protocols in relation to the appropriate use of antimicrobials in human and animal use, as well as strategies to monitor the supply and use of antimicrobials in our hospitals and community. Education awareness programmes have been developed which are focused on medical professionals, veterinary practitioners and the general public. These aim to create a better understanding of AMR and how it links to our broader society. Managing and controlling any future emergence of AMR micro-organisms will require a multi-disciplinary approach with impacts from all health care professionals and stakeholders in the food industry.
